Only if we restrict to one spatial dimension, so the motion and the forces are all in the same direction. As soon as you have motion and forces pointing in different directions, relativistic mass as inertia no longer works because "inertia" is no longer a single number; an object's response to a given force depends on the direction of the force relative to the object's motion.

Inclusion of conceptual questions on tests is another way to emphasize the importance of this aspect of problem solving (see Chapter 6). In many cases students have developed partially correct ideas that can be used as the foundation for further learning (Clement et al., 1989).

Most circuits have more than one component, called a resistor that limits the flow of charge in the circuit. A measure of this limit on charge flow is called resistance.The simplest combinations of resistors are the series and parallel connections illustrated in Figure 1.The total resistance of a combination of resistors depends on both their individual values and how they are connected.

Speed and Velocity. Speed and velocity can be a little confusing for most of us. Well, the difference between speed and velocity is that speed gives us an idea of how fast an object is moving whereas velocity not only tells us its speed but also tells us the direction the body is moving in. We can define speed as a function of distance traveled whereas velocity is a function of displacement.

In each of these situations, an object has a velocity relative to a medium (such as a river) and that medium has a velocity relative to an observer on solid ground. The velocity of the object relative to the observer is the sum of these velocity vectors, as indicated in Figure 1 and Figure 2. These situations are only two of many in which it is useful to add velocities.
